CUTTING APPARATUS FOR WINDOW COVERINGS
AND METHODS THEREFOR

5 CROSS-REFERENCE TO RELATED APPLICATIONS

The present invention is a divisional application of Application Serial No. 09/054,845, filed April 3, 1998, which claims benefit of U.S. Provisional Application Serial No. 60/068,039 filed December 18,
10 1997, and the disclosures of both of these applications are hereby incorporated by reference herein.

FIELD OF THE INVENTION

The present invention relates generally to
15 the art of window coverings and more specifically relates to cutting machines and methods for cutting window coverings to specified lengths.

BACKGROUND OF THE INVENTION

20 Retail outlets frequently sell many different types of window coverings such as draperies, curtains, venetian blinds and shades. These window coverings generally extend horizontally across a window opening and are typically sized to accommodate the dimensions
25 of the window opening. One popular type of window covering is a window shade having a head rail, a bottom rail and a window covering material between the head rail and the bottom rail. Common window covering materials include slats, such as PVC slats, or fabric.
30 One problem with such window shades is that the width of the head rail, the bottom rail and the window covering material must be customized to match the exact dimensions of the window opening. In response to this problem, a number of options have been developed so
35 that consumers may obtain customized window shades which are sized to fit a specific window opening.

In accordance with a first option, a customer typically visits a specialty shop or department store and places an order for customized window shades. This option requires the customer to first measure the window opening and submit the measurements to a salesperson. The salesperson will then submit the order to a factory or distribution center where the window shade is cut to the specified length. This option is rather time consuming, because the customer must make at least two visits to the retail outlet in order to obtain the customized product, i.e. a first visit to place the order and a second visit to pick up the product. In addition, this particular option is relatively expensive.

A second option involves selecting the window shade from a stock of pre-sized shades maintained at the retail establishment. Typically, only certain standard sizes are carried because some window openings, especially in newer homes and offices, are of standard dimensions. These pre-stocked, standardized window shades are usually much less expensive than those obtained from custom specialty shops because stocked shades may be mass-produced in an economical manner. In addition, the cost to the consumer is reduced because there is no need to perform a cutting or sizing operation at the retail establishment.

A third option has recently evolved. This particular option involves the in-store sizing or cutting of the window shades to match the exact window dimensions specified by the customer. Various machines and methods for performing these tasks are disclosed in U.S. Patents 5,339,716; 5,037,253; 5,456,149; 4,993,131; 5,072,494 and 5,103,702. These various disclosures have been generally inadequate at providing systems for efficiently and accurately sizing window shades to specified lengths. For example, most of the systems disclosed are too complex to be operated by a typical retail salesperson having an average degree of

training. In addition, many of these systems require numerous steps in order to cut the window shade, i.e. the head rail is cut in a first cutting operation and the window covering material is cut in a second cutting operation. Further, these systems, and particularly the cutting blades of these systems exert a tremendous amount of force upon the window shade being cut which often results in the cut ends of the shades being uneven, chipped or cracked. These defects produce a final product of inferior quality.

Thus, there is a need for a cutting apparatus for window shades capable of efficiently customizing window shades to fit window dimensions specified by customers. There is also a need for a cutting apparatus for cutting a window shade to a specified length, whereby the entire window shade, namely the head rail, the bottom rail and the window covering material are all cut simultaneously in a single cutting stroke, thereby saving time and reducing operator errors. Moreover, the cutting apparatus should produce a final product having a high-quality, professionally-cut appearance. Applicant is presently the exclusive licensee of such an improved cutting machine which is disclosed in U.S. Patent Application Ser. No. 08/627,015 entitled "End Trimming Device For Blinds", the disclosure of which is hereby incorporated by reference herein. Another improved cutting device is sold by the Applicant, Springs Window Fashions, under the trademark "Crystal Pleat Cut-Down Machine."

However, still further improvements would be desirable.

SUMMARY OF THE INVENTION

In accordance with certain preferred embodiments of the present invention, a cutting apparatus is provided for cutting a window shade to a specified length. The window shade preferably includes a head rail, a bottom rail and a window covering

material or covering material. The window covering material or covering material typically includes a fabric or slats provided between the head rail and the bottom rail. The head rail and the bottom rail preferably comprise a substantially rugged material, such as extruded plastic, which can be readily cut to specified lengths.

The cutting apparatus preferably includes a base having a top surface and a frame overlying the top surface of the base. The frame is preferably mounted to the base to form a rigid structure. The frame and the top surface define a receiving area therebetween for receiving one or more window shades which will be cut in the cutting apparatus. A cutting assembly is slidably mounted to the frame for sliding along a movement axis toward and away from the receiving area. The frame preferably includes one or more guide tracks which are angled with respect to the top surface of the base and the cutting assembly is slidably mounted in the guide tracks so that the movement axis is diagonal to the top surface of the base. The cutting assembly includes a cutting blade having a cutting edge facing the receiving area. The cutting apparatus also includes a mechanical element, such as a driver, which may be operated to impart sliding motion to the cutting assembly. The driver may include a rack and pinion gear arrangement, a ratcheting mechanism, a screw-activated element, a pneumatic element or an electrical-motor operated device. In one particular preferred embodiment the cutting assembly includes a rack having a plurality of teeth. A pinion, having a plurality of teeth at a periphery thereof, is rotatably mounted in the frame. The pinion is matingly engaged with the rack so that when the pinion is rotated, the pinion imparts sliding motion to the cutting assembly to move the cutting blade diagonally through the receiving area for cutting the window shade to the specified length.

The base may include a support guide, provided over the top surface thereof, for guiding movement of the window shade across the top surface of the base and towards the receiving area. In preferred
5 embodiments, the support guide includes a mandrel which engages at least one of the head rails or bottom rails and which most preferably engages the head rail during cutting operations. The mandrel extends along the top surface of the base from a first end of the top surface
10 to a second end of the top surface. The second end of the top surface is preferably adjacent the cutting blade.

In certain preferred embodiments the base includes a clamp assembly for securing the window shade
15 over the top surface of the base. The clamp preferably includes a clamp block having a threaded bore, a threaded shaft which is capable of being rotated and a crank handle. The threaded shaft has a first end which is threadably connected to the clamp block and a second
20 end which is rotatably connected to the crank handle. Rotation of the crank handle moves the clamp block into and out of engagement with the window shade. The crank handle is preferably rotated in a clockwise or counter-clockwise direction so as to apply a clamping force to
25 the window shade. In other preferred embodiments the clamp may include a pneumatic device, an electrically operated device, a screw device, a ratcheting device or a weight.

The cutting blade is preferably provided at
30 the second end of the top surface and has a longitudinal axis which is substantially perpendicular to the longitudinal axis of the guide rail. The cutting blade has a first face which is substantially flat and a second face which includes a pocketed portion. The
35 pocketed portion of the cutting blade is preferably the only section of the blade which engages and cuts the window shade. The pocket is substantially thinner than the area of the cutting blade which surrounds the

pocket. The pocketed portion includes a tapered region which is contiguous with the cutting edge and which extends up and away from the cutting edge. The tapered region has a first tapered section or bevel which
5 extends from the cutting edge. The first tapered section and the substantially flat first face define a first acute angle. The tapered region includes a second tapered section which extends from the first tapered section. The second tapered section and the
10 substantially flat first face define a second acute angle which is smaller than the first acute angle. The substantially flat first face of the cutting blade preferably faces upstream toward the first end of the top surface of the base while the second face (i.e. the
15 face including the pocketed portion) preferably faces downstream and away from the first end of the top surface.

The cutting blade preferably includes any material, man-made or naturally occurring, having the
20 strength and/or durability to efficiently cut through the shade assembly, and more preferably includes carbide steel or diamond.

The cutting apparatus also preferably includes a measuring assembly adjacent and/or
25 downstream from the cutting blade for measuring the window shade. Specifically, the measuring assembly provides a measuring tool for defining the exact length of the end portion of the window shade to be cut. The measuring assembly preferably includes a stop block
30 which abuts against the end portion of the window shade. The stop block is connected to a cam follower which in turn is connected to the pinion so that the stop block moves away from the end of the window shade as the cutting blade slices through the window shade.
35 By coming away, the stop block allows the cut end portion of the window shade to pivot away from the cutting blade which minimizes the forces exerted by the cutting blade upon the window shade. Thus, the stop

block is movable between a first position and a second position. In the first position, the stop block abuts against the end portion of the window shade. In the second position the stop block is not in contact with the end portion of the window shade because the stop block cams away from the end portion.

Another aspect of the present invention provides a method of cutting a window shade to a specified length. In certain preferred embodiments a method of cutting the window shade includes providing a cutting apparatus having a receiving area for receiving the window shade whereby the cutting apparatus includes a cutting blade slidably mounted therein for sliding along a movement axis toward and away from the receiving area. Next, the window shade is provided in the receiving area and the cutting blade is passed diagonally through the receiving area and the window shade for cutting off an end portion of the window shade to provide a window shade having a specified length. Initially, the window shade is inserted into the first end of the cutting apparatus and slid along the top surface of the base toward the cutting blade so that the cutting blade overlies the end portion of the window shade which is to be cut. The measuring assembly is then utilized to determine the exact length of the end portion of the window shade being cut. Once the exact length of the end portion to be cut has been determined, the crank handle of the clamping assembly is rotated so that the clamping block moves into engagement with the window shade so as to secure the window shade between the clamp block and the guide rail. The crank continues to be rotated until the clamping block has secured the window shade over the top surface of the base. The pinion is then rotated to move the cutting assembly. A lever handle is preferably connected to the pinion to facilitate rotation of the pinion. Rotation of the pinion slides the cutting assembly in the angled guide tracks along

the movement axis which is diagonal to the top surface of the base so that the cutting blade slices diagonally through the window shade. As the cutting blade slices through the window shade, the stop block cams away from the end portion of the window shade being cut so that the cut end portion is free to pivot away from the cutting blade. Because the end of the window shade being cut is free to pivot away from the blade, the compression forces exerted by the cutting blade upon the window shade are greatly reduced which greatly reduces the likelihood that the head rail or the bottom rail will crack while being cut. After the window shade has been completely cut, the direction of the lever handle is preferably reversed to return the cutting blade to its initial position. The measuring assembly moves back towards the cutting blade as the handle is returned to its initial start position. At this point the window shade may be removed from the cutting apparatus. In certain instances it may be preferable to trim or cut a second end of the window shade to a specified length. This may be accomplished by inserting the second end of the window shade into the cutting apparatus and repeating the steps described above.

These and other objects, features and advantages of the present invention will be more readily apparent from the detailed description of the preferred embodiment set forth below and when taken in conjunction with the accompanying drawings.

30

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows an exploded perspective view of a cutting apparatus for cutting a window shade to a desired length according to one preferred embodiment of the present invention.

35

FIG. 2A shows a front view of the cutting apparatus shown in FIG. 1.

FIG. 2B shows a right side view of the

cutting apparatus shown in FIG. 2A.

FIG. 3A shows a perspective front view of one preferred window shade cut to a specified length in the cutting apparatus shown in FIG. 1.

5 FIG. 3B shows a side view of the window shade shown in FIG. 3A.

FIG. 4A shows a top view of a base of the cutting apparatus shown in FIG. 1 according to one preferred embodiment of the present invention.

10 FIG. 4B shows a right side view of the base shown in FIG. 4A along the sectional line designated 4B-4B in FIG. 4A.

FIG. 5A shows a fragmentary view of a face of a cutting blade of the cutting apparatus shown in FIG. 1 according to certain preferred embodiments of the present invention.

FIG. 5B shows a fragmentary side view of the cutting blade shown in FIG. 5A along the sectional line designated 5B-5B in FIG. 5A.

20 FIG. 5C shows a cross-sectional fragmentary side view of the cutting blade shown in FIG. 5A along the sectional line designated 5C-5C in FIG. 5A.

FIG. 6A shows a fragmentary top view of the window shade shown in FIG. 3A after the window shade has been inserted into the cutting apparatus of FIG. 1.

FIG. 6B shows a cross-sectional end view of the window shade and cutting apparatus shown in FIG. 6A.

30 FIG. 7A shows a simplified view of FIG. 6B with the cutting blade initially contacting the window shade in accordance with certain preferred embodiments of the present invention.

FIG. 7B shows the cutting blade of FIG. 7A during a further stage of a cutting operation.

35 FIG. 7C shows the cutting blade of FIG. 7B during a still further stage of the cutting operation.

FIG. 8A shows a fragmentary side view of FIG. 7A.

FIG. 8B shows a fragmentary side view of
FIG. 7C.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

5 Referring to Figs. 1, 2A and 2B, preferred
embodiments of the present invention provide a cutting
apparatus 20 for cutting or sizing a window shade to a
specified length. The cutting apparatus 20 preferably
includes a base 22 having a top surface 24 and a frame
10 26 which overlies the top surface 24 of the base 22.
The frame 26 is mounted to the base 22 so that the
frame 26 and the base 22 form a substantially rigid
structure. The frame 26 includes guide tracks 28A and
28B which are angled with respect to the top surface 24
15 of the base 22. The angle formed by the guide tracks
28A, 28B and the top surface 24 is preferably between
one to 89 degrees. A cutting assembly 30 including a
cutting blade 32 is slidably mounted in the guide
tracks 28A and 28B and moves along a movement axis
20 designated A-A which is diagonal to the top surface 24
of the base 22. The top surface 24 of the base 22 and
the frame 26 define an aperture or receiving area 34
into which an end portion of a window shade is
preferably inserted in order to be cut by the cutting
25 apparatus 20. The cutting apparatus 20 is preferably
capable of cutting entirely through the end of the
window shade with a single pass of the cutting blade
32. The terms "top", "bottom", "front", "side", "first"
and "second" are used herein to indicate directions
30 relative to the cutting apparatus itself. It should be
understood that these terms are used to refer to the
frame of reference of the apparatus itself, and not to
the ordinary, gravitational frame of reference.

Referring to Figs. 3A and 3B, one preferred
35 window shade 36 capable of being cut by the cutting
apparatus 20 described above includes a headrail 38, a
bottom rail 40 and window covering material 41
therebetween. The head rail 38 and the bottom rail 40

preferably include an extruded plastic material. The window covering material 41 may include a fabric, such as a point bonded polyester blend material, or may include slats which generally comprise a somewhat flexible material, such as polyvinyl chloride (PVC). The top portion of the head rail 38 has a "C"-shaped opening 42 which may be used for securing the shade 36 to a window opening or for rigging the window shade 36 with control lines. The head rail 38 also preferably includes a lower "C"-shaped opening 46 for securing a top section of the window covering material 41. The bottom rail 40 also has a "C"-shaped opening 50 for receiving and securing a bottom section of the window covering material 41. The window shade 36 also includes removable end caps 44 at the ends of the head rail 38 and the base rail 40.

The end caps 44 stabilize the ends of the head rail 38 and the base rail 40 and improve the overall aesthetic appearance of the window shade 36. The ends caps 44 are preferably removed before the window shade 36 is cut and reinstalled into the rail ends after the cutting operation. Referring to Figs. 4A and 4B, the base 22 generally includes a hardened steel. The top surface 24 of the base 22 preferably has a first end 52 which initially receives the window shade 36 and a second end 54 which is adjacent the cutting blade (Fig. 2A). As shown in Fig. 2A, a safety guard 56, designated the left hand guard, preferably overlies the first end 52 of the top surface 24 so as to prevent an operator from placing his or her hands under the cutting blade 32. The hand guard 56 preferably comprises a hardened, rugged material such as a metal or a clear plastic material, such as Lexan, Plexiglas or Acrylic. Referring to Figs. 4A and 4B, the base 22 preferably includes a guide rail 58 which overlies the top surface 24 and extends from the first end 52 of the top surface 24 to the second end 54 thereof. The guide rail 58 serves to align the head

rail 38 over the top surface 24 of the base 22 and
guide the head rail 38 over the top surface 24. The
guide rail 58 is preferably a mandrel shaped to fit
relatively snugly within the "C"-shaped opening 42 at
5 the top of the headrail 38. The base 22 also includes
a clamping assembly for securing the window shade 36 to
the top surface 24 of the base 22 prior to cutting the
window shade 36. The clamping assembly includes a
clamp block 60 extending over the top surface 24 in a
10 longitudinal direction which is substantially parallel
to the guide rail 58. The clamp block 60 preferably
moves independently of the base and is attached to a
sliding portion 62 provided in a slot 64 cut into the
top surface 24 of the base 22 so that the clamp block
15 60 may slide towards and away from the guide rail 58.
The clamp block 60 is connected to a threaded block 66
having a threaded bore therein. The threaded block 66
is preferably rigidly connected to the base 22 so that
the threaded block does not move independently of the
20 base 22. The clamping assembly also includes a
rotatable, threaded shaft 68 having a first end 70
which is connected to the clamp block 60 and a second
end 72 which is rotatably connected to a crank handle
74. Rotation of the crank handle 74 rotates the
25 threaded shaft 68 which in turn moves the clamping
block 60 toward and away from the guide rail 58.

The top surface 24 of the base 22 preferably
includes a backup 76 which opposes the cutting blades
32. The backup 76 is preferably located at the second
30 end 54 of the top surface 24 of the base 22 and extends
slightly beyond the second end 54 of the top surface
24. In certain preferred embodiments the backup 76
extends between approximately 1/32 inch and 3/32 inch
beyond the second end 54. The backup 76 preferably
35 includes a hardened material, such as a nylon material,
which is relatively softer than the material comprising
the cutting blade 32, so that the backup is stiff
enough to adequately support the window shade 36 and so

that the cutting blade 32 is not prematurely dulled when it repeatedly abuts against the backup 76 during cutting operations.

Referring to Fig. 2B, the frame 26 includes
5 guide tracks 28A and 28B which are angled relative to the top surface 24 of the base 22. The cutting assembly 30 is slidably mounted in the guide tracks 28A and 28B and is capable of sliding within the guide tracks 28A and 28B along the movement axis designated
10 A-A. The movement axis A-A has both a downward vertical component (Y-axis) and a horizontal component (X-axis). Thus, the movement axis A-A is diagonal with respect to the top surface 24 of the base 22 so that the cutting blade 32 moves along both the y axis and x
15 axis with respect to the top surface 24. The cutting assembly 30 preferably includes a rack 78 having a plurality of teeth 80 so that the cutting assembly 30 may be operated using a rack and pinion mechanism. A driver such as a pinion 82 having a plurality of teeth
20 84 is rotatably mounted in the frame 26 and is matingly engaged with the rack 78 so that the teeth 84 of the pinion 82 mesh with the teeth 80 of the rack 78. A lever handle 86 is connected to the pinion 82 and preferably has considerable length for providing
25 leverage so that the pinion 82 may be readily rotated by an operator. As the pinion 82 rotates, the teeth 84 of the pinion 82 mesh with the teeth 80 of the rack 78 so as to impart sliding motion to the cutting assembly 38 and move the cutting assembly 30 within the guide
30 tracks 28A and 28B.

Referring to Fig. 2A, a safety pin 88 is provided at an exterior surface of the frame 26. The safety pin 88 meshes with the pinion 82 so that the handle 86 cannot move until the safety pin 88 is
35 retracted. In preferred embodiments, the safety pin 88 is provided on one side of the frame 26 and the handle 86 is provided on an opposite side of the frame 26. This particular design feature ensures that an

operator's hands will not be positioned under the cutting blade 32 during a cutting operation because one of the operator's hands must retract the safety pin 88 while the other hand is pulling the handle 86. Once
5 the safety pin 88 has been retracted, the handle 86 is preferably pulled downward towards the operator so as to rotate the pinion 82.

Referring to Figs. 5A - 5C, the cutting blade 32 is relatively massive and has a cutting edge 90
10 which faces the window shade to be cut. In certain embodiments the cutting blade 32 includes carbide steel. In other preferred embodiments the cutting edge 90 of the cutting blade 32 may include diamond. As shown in Figs. 5B and 5C, the cutting blade 32 includes
15 a first face 92 which is substantially flat. The cutting blade 32 also has a second face 94 remote from the first face 92. The second face 94 includes a concave pocket 96 cut into the second face 94. The thickness of the pocketed portion 96 of the cutting
20 blade 32 is substantially thinner than the remaining portion of the blade which surrounds the pocketed portion. For example, as shown in Fig. 5B, upper portion 98 of the cutting blade 32, i.e. the massive portion surrounding the pocket 96, is between
25 approximately 0.40 to 0.50 inches thick while the pocketed portion 96 of the blade 32 is between approximately 0.10 and 0.20 thick. The pocket 96 preferably includes a tapered section which tapers outwardly from the cutting edge 90 of the blade 32. In
30 other words, the pocket 96 of the blade 32 becomes thicker as the distance from the cutting edge 90 increases. However, the thickness of the pocket 96 always remains less than the thickness of the massive portion 98 of the blade 32. The massive portion 98 of
35 the cutting blade 32 stabilizes the blade 32 and prevents the cutting edge 90 from flexing and bowing during a cutting operation which could result in an erratic cut line which is not vertical. The pocketed

portion 96 is preferably the only portion of the blade 32 which engages the end portion of the shade 36 being cut. Thus, the pocketed portion 96 enables the blade 32 to effectively slice through the window shade 36 because the pocketed portion 96 is relatively thin.

Pocketed portion 96 preferably includes a tapered region having a first tapered section 100 or bevel which extends up and away from the cutting edge 90 of the blade 32. The beveled section 100 and the first face 92 of the cutting blade 32 form a first acute angle. The pocket 96 also includes a second tapered section 104 which extends up and away from the beveled section 100. The second tapered section 104 and the first face 92 of the cutting blade 32 form a second acute angle which is smaller than the first acute angle 102.

Referring to Figs. 1 and 2A, the cutting apparatus 20 also preferably includes a measuring assembly generally designated as 108 for measuring the end portion of the window shade being cut. In certain preferred embodiments, the measuring assembly includes a guard, hereinafter referred to as right hand guard 110, which prevents an operator from placing his or her hands under the cutting blade 32. The right hand guard 110 includes a removable end plate 112 remote from the cutting blade 32 which provides access to an area of the cutting apparatus 20 immediately downstream from the cutting blade 32. The right hand guard 110 preferably includes a rugged, but clear material which enables an operator to observe the cutting operation, such as Lexan, Plexiglas or Acrylic. The measuring assembly 108 includes a measuring instrument 114, such as a ruler, which is permanently attached to the right hand guard 110 for measuring the end portion of the window shade being cut. The ruler 114 is preferably attached to the underside of the right hand guard 110 and is visible through the right hand guard 110. The guard 110 includes two slots 116A and 116B on opposite

sides thereof which extend horizontally away from the cutting blade 32. A stop block 118 is slidably mounted in the slots 116A and 116B and is movable toward and away from the cutting blade 32. The stop block 118 includes a stop knob 120 at one side thereof which can be hand tightened to secure the stop block 118 in place within the slots 116A and 116B. The stop block 118 preferably underlies the ruler 114 so that the length of the end portion of the window shade being cut can be accurately measured by aligning the stop block 118 with a certain spot on the ruler. For example, if a customer requests that two inches be cut off from one end of the window shade, then the stop block 118 is moved to a position two inches away from the cutting blade 32, as indicated by the ruler 114. Once the stop block 118 has been positioned at the desired distance from the cutting blade 32, the stop knob 120 is hand-tightened to secure the stop block 118 in place.

The stop block 118, and preferably the entire measuring assembly 108, is connected to a cam follower 122. In turn, the cam follower 122 is interconnected with the pinion 82 so that the entire measuring assembly 108 including the stop block 118 cams away from the cutting blade 32 as the cutting blade slices through an end portion of the window shade. Because the stop block 118 cams away, the end of the window shade 36 being cut is able to freely pivot down and away from the cutting blade 32, thereby reducing the compression force exerted by the blade 32 upon the window shade. In certain preferred embodiments, a cam collar 124 is connected to the pinion 82 for rotating with the pinion. The cam collar 124 has a groove 126 formed on the outer periphery thereof. The cam follower 122 is positioned within the groove 126 for interconnecting the cam collar 124 and the measuring assembly 108. When the pinion 82 rotates, the cam follower 122 moves through the groove 126 in the cam collar 124. The groove 126 guides the cam follower 122

away from the cutting blade 32 which causes the measuring assembly 108 and the stop block 118 to cam away from the cutting blade 32.

As mention above, the cutting apparatus 20 according to the present invention will preferably be located in a retail store so that customers may have window shades efficiently and economically cut to specified lengths. The cutting apparatus 20 will preferably be provided over a supporting element, such as a table. The cutting apparatus 20 will preferably be bolted or firmly secured to the table. The table may have an opening adjacent and/or downstream from the cutting blade 32 so the cut end portion of the window shade 36 can fall through the opening and into a waste container. Typically, a customer desiring window shades cut to a specified length will provide a salesperson (hereinafter referred to as the "operator") with the dimensions of one or more window openings. The operator may then refer to a chart, typically provided by the manufacturer of the window shades, in order to select a particular pre-stocked shade to be cut. Preferably the manufacturer will provide anywhere from five to ten, or even more, different models of shades. The manufacturer's chart may also provide the operator with information concerning how many inches or feet must be cut off one or both ends of the window shade.

Referring to Figs. 6A and 6B, the end 128 of the window shade 36 to be cut is preferably positioned at the first end 52 of the top surface 24 of the base 22. After the end caps 44 (not shown) have been removed from the head rail 38 and the base rail 40, the window shade 36 is preferably aligned over the top surface 24 so the head rail 38 faces the guide rail 58 or mandrel and the base rail 40 faces the clamp block 60. The "C"-shaped opening 42 at the top of the head rail 38 is aligned with and slid over the mandrel 58, whereupon the head rail 38 is deemed to be captured by

the mandrel. Once the head rail 38 has been captured by the mandrel 58, the window shade 36 is moved or inserted toward the second end 54 of the top surface 24 and the stop block 118. The window shade 36 continues
5 to be inserted into the cutting apparatus 20 until the end portion 128 of the window shade 36 abuts against the stop block 118. At this stage, the cutting blade 32 overlies the end portion 128 of the window shade 36.

After the window shade 36 has been fully
10 inserted into the cutting apparatus 20 and abutted against the stop block 118, the operator firmly secures the window shade 36 in place over the top surface 24 using the clamping assembly. The operator rotates the crank handle 74, preferably in a clockwise direction,
15 which rotates the shaft, which in-turn causes the clamp block 60 to move toward the window shade 36 and the mandrel 58. The operator continues to hand-tighten the crank handle 74 until the clamp block 60 abuts against the base rail 40 and compresses the window shade 36
20 between the clamp block 60 and the mandrel 58. Once the window shade 36 has been secured over the top surface 24 of the base 22, the operator may cut the end 128 of the window shade 36.

Referring to Figs. 2A and 2B, before the
25 handle 86 may be pulled to cut the window shade 36, the safety pin 88 in the frame 26 must be retracted so as to free the pinion 82 for rotation. As the safety pin 88 is maintained in the retracted position, the handle 86 is preferably rotated downward toward the operator
30 which rotates the pinion 82. As the pinion 82 rotates, the teeth 84 of the pinion 82 mesh with the teeth 80 of the rack 78 to move the cutting assembly 30 downward within the angled guide tracks 28A and 28B. As the cutting assembly 30 moves downward, the cutting blade
35 32 moves along the movement axis designated A-A in a direction which is diagonal to the top surface 24 of the base 22 and the window shade 36. In other words, the cutting blade moves in a direction which has both

vertical (y-axis) and horizontal (x-axis) components. Because the cutting blade 32 moves diagonally with respect to both the top surface 24 of the base 22 and the window shade 36 secured thereto, the cutting blade
5 32 slices through the window shade 36 in a diagonal direction. This slicing action, as opposed to an entirely vertical cut (Y-axis) or chopping action, greatly reduces the compression forces exerted by the blade 32 upon the window shade 36 and results in the
10 formation of a cleaner cut. The slicing action also prevents the cut edges of the head and bottom rails 38, 40 from breaking or cracking.

Referring to Fig. 6B, the window shade is preferably configured over the top surface 24 of the
15 base 22 so that the cutting edge 90 simultaneously abuts against the bottom rail 40, the head rail 38 and the window covering material 41. As the cutting edge 90 slices through the window shade 36 in a diagonal direction, the mandrel 58 supports the head rail 38 and
20 functions as an inner die. Because the mandrel extends all the way to the second end 54 of the top surface 24 of the base 22 and terminates immediately before the first face 92 of the cutting blade 32, an extremely clean cut can be formed at the end of the head rail 38.
25 The mandrel 58 also prevents the head rail 38 from rotating while it is being cut, thereby further contributing to the formation of a straight and clean cut.

Figs. 7A-7C show the cutting blade 32
30 described above as the blade slices through the window shade 36. The window shade 36 and the base 22 are depicted as blocks for clarity of illustration. Initially, the cutting edge 90 engages the entire top of the window shade 36. In other words, the cutting
35 edge 90 simultaneously engages the base rail, the window covering material and the head rail. As shown in Fig. 7B, the cutting edge moves vertically downward along the y-axis and to the side along the x-axis, i.e.

diagonally through the window shade 36. The cutting edge 90 continues to move diagonally through the window shade 36 until the blade 32 has sliced completely through the shade 36, as shown in Fig. 7C. During the entire cutting operation only the pocket 96 engages the shade 36 which further minimizes the forces the blade exerts upon the shade 36.

Figs. 8A and 8B show side views of Figs. 7A and 7C, respectively. When the blade 32 initially engages the window shade 36, the stop block 118 abuts against the end of the window shade 36. However, shortly after the blade 32 begins to slice through the window shade 36, the stop block 118 cams away from the cutting blade 36 which allows the end portion 128 of the window shade 36, which is preferably unsupported, to freely pivot away from the cutting blade 32. By enabling the cut end portion 128 to pivot away from the blade 32, the forces exerted upon the window shade 36 by the cutting blade 32 are greatly reduced. This is of particular importance toward the end on the cutting stroke when the blade 32 has almost completely cut through the window shade 36 because at this point there exists an increased likelihood that the blade 36 will compress the head rail 38 and the bottom rail 40 which greatly increases the likelihood that those elements will crack.

As shown in Figs. 8A and 8B, because the first face 90 of the cutting blade 32 is vertical and/or substantially flat, the blade 36 provides the window shade 36 with a clean, squared-off cut. As mentioned above, the pocketed portion 96 of the blade 32, which is much thinner than the rest of the blade 36, is the only portion of the blade which engages the window shade. This preferred design minimizes the thickness of the cutting blade 32 actually cutting through the window shade 36, thereby preventing the head rail 38 and the bottom rail 40 from cracking, breaking or tearing as the window shade 36 is cut.

Because the pocketed portion 96 is tapered, the end portion 128 of the window shade being cut pivots away from the blade 32. When the blade 32 reaches the bottom portion of the cut, the thickness of the blade 5 32 at that section is particularly thin so that the blade 32 does not crack or break the head rail 38 or the bottom rail 40. The pocketed design results in only a thin portion of the blade 30 contacting the window shade 36; however, the massive portion of the 10 blade 32 surrounding the pocket 96 stabilizes the pocketed portion 96 and prevents the blade 32 from bending during a cutting operation.

After the end portion 128 of the window shade 36 has been completely cut, the end portion 128 falls 15 down and away from the cutting apparatus 20 and preferably through an opening in the supporting table. The operating handle 86 may then be rotated upward to its initial start position which will move the cutting blade 32 away from the backup 76. As the handle 86 is 20 rotated upward, the safety pin 88 will re-engage the pinion 82 to lock the pinion 82 in place and prevent further rotation of the pinion. The crank handle 74 is then preferably rotated in a counter-clockwise direction to release the clamping force on the window 25 shade 36 so that the window shade 36 may be removed from the cutting apparatus 20. The window shade 36 may then be removed by sliding the window shade 36 away from the first end 52 of the top surface 24 of the base 22, so that the "C"-shaped opening 42 in the head rail 30 38 may be released from the mandrel 58. If necessary, a second end of the window shade 36 may also be cut to a specified length using substantially the same techniques as described above. After the cutting operation is complete, the end caps 44 are preferably 35 re-installed at the ends of the head rail 38 and the base rail 40.

As will be appreciated, numerous variations and combinations of the features discussed above may be

utilized without departing from the present invention
as defined in the claims. For example, the cutting
assembly may follow an eccentric motion over a certain
area of travel so as to multiply the force exerted by
5 the cutting blade. In other embodiments, the cutting
assembly may include a laser for cutting the window
shade with laser light energy. Accordingly, the
foregoing description of the preferred embodiments
should be taken by way of illustration rather than by
10 way of limitation of the present invention.

WE CLAIM:

1. An apparatus for cutting a window covering to a specified length comprising:

a base having a top surface;

5 a frame overlying said top surface and mounted to said base, said frame and said top surface defining a receiving area therebetween for receiving said window covering;

10 a cutting assembly slidably mounted to said frame for sliding along a movement axis toward and away from said receiving area, said movement axis being diagonal to said top surface of said base;

15 a cutting blade connected to said cutting assembly, said cutting blade including a cutting edge facing said receiving area; and

20 a driver connected and in engagement with said cutting assembly, wherein operation of said driver imparts sliding motion to said cutting assembly to move said cutting blade diagonally through said receiving area.

2. An apparatus as claimed in claim 1, wherein said cutting blade cuts said window covering to said specified length when moving through said receiving area.

25 3. An apparatus as claimed in claim 1, wherein said frame includes one or more guide tracks, said cutting assembly being slidably mounted in said one or more guide tracks.

30 4. An apparatus as claimed in claim 3, wherein said one or more guide tracks are angled with respect to said top surface of said base.

35 5. An apparatus as claimed in claim 1, wherein said driver is selected from the group consisting of rack and pinion gear arrangements, ratcheting mechanisms, screw-activated elements, pneumatic elements and electrical-motor operated devices.

6. An apparatus as claimed in claim 5,

wherein said cutting assembly includes a rack having a plurality of teeth and said pinion includes a plurality of teeth at the periphery thereof, said pinion being matingly engaged with said rack so that rotation of
5 said pinion imparts motion to said cutting assembly.

7. An apparatus as claimed in claim 6, said cutting apparatus further comprising a lever connected to said pinion, wherein movement of said lever rotates said pinion.

10 8. An apparatus as claimed in claim 7, said lever including a handle at an end thereof remote from said pinion.

9. An apparatus as claimed in claim 1, said window covering including a head rail, a bottom rail
15 and a covering material therebetween.

10. An apparatus as claimed in claim 9, wherein said covering material includes an upper section connected to said head rail and a lower section connected to said base rail.

20 11. An apparatus as claimed in claim 9, said top surface of said base having a first end and a second end adjacent said cutting blade.

12. An apparatus as claimed in claim 11, said apparatus further comprising a backup at said
25 second end of said top surface, said backup opposing said cutting edge of said cutting blade.

13. An apparatus as claimed in claim 12, wherein said backup includes nylon.

14. An apparatus as claimed in claim 12,
30 wherein said backup includes a bar extending across said second end of said top surface.

15. An apparatus as claimed in claim 11, said base including a guide rail at said top surface of said base extending from said first end to said second
35 end of said top surface, said guide rail guiding movement of said window covering across said top surface and aligning said window covering with said cutting blade.

16. An apparatus as claimed in claim 15,
wherein said guide rail has a longitudinal axis
extending between said first and second ends of said
top surface which is substantially parallel to a
5 longitudinal axis of said head rail and a longitudinal
axis of said bottom rail.

17. An apparatus as claimed in claim 16,
wherein a portion of said guide rail at said second end
of said top surface is adjacent said movement axis so
10 that said cutting blade passes closely by said guide
rail at said second end of said top surface while said
cutting blade moves through said receiving area.

18. An apparatus as claimed in claim 15,
said guide rail including a mandrel for engaging at
15 least one of said head rail and said bottom rail.

19. An apparatus as claimed in claim 18,
said headrail including an opening at the top thereof,
said mandrel being slidable within said opening.

20. An apparatus as claimed in claim 1,
20 wherein said base includes a clamping assembly for
securing said window shade over said top surface of
said base.

21. An apparatus as claimed in claim 15,
said clamping assembly including a clamp block
25 extending substantially parallel to said guide rail and
having a threaded bore, a rotatably threaded shaft and
a crank handle, said rotatably threaded shaft having a
first end connected to said clamp block via said
threaded bore and a second end rotatably connected to
30 said crank handle, wherein said crank handle is
rotatable for moving said clamp block toward and away
from said guide rail.

22. An apparatus as claimed in claim 21,
wherein said clamp block is movable toward said guide
35 rail for applying a clamping force to said window
covering.

23. An apparatus as claimed in claim 16,
wherein said cutting blade includes a longitudinal axis

which is substantially perpendicular to said longitudinal axis of said guide rail.

24. An apparatus as claimed in claim 23, wherein said cutting blade includes a massive portion and a pocket, said massive portion being thicker than said pocket.

25. An apparatus as claimed in claim 24, wherein said pocket is contiguous with said cutting edge and said massive portion surrounds said pocket.

26. An apparatus as claimed in claim 24, wherein said massive portion of said cutting blade is approximately 0.40 - 0.50 inches thick and said pocket of said cutting blade is approximately 0.10 - 0.20 inches thick.

27. An apparatus as claimed in claim 1, wherein said cutting blade includes a first face which is substantially flat and a second face including said pocket.

28. An apparatus as claimed in claim 24, wherein said pocket includes a tapered region extending from said cutting edge, said tapered region having a thickness which increases as the distance from said cutting edge increases.

29. An apparatus as claimed in claim 28, wherein said tapered region includes a first tapered section extending away from said cutting edge, said first tapered section and said first face of said cutting blade defining a first acute angle.

30. An apparatus as claimed in claim 28, wherein said tapered region includes a second tapered section extending from said first tapered section and remote from said cutting edge, said second tapered section and said first face of said cutting blade defining a second acute angle which is smaller than said first acute angle.

31. An apparatus as claimed in claim 30, wherein said apparatus includes a measuring assembly adjacent said cutting blade for measuring said

specified length of said window covering.

32. An apparatus as claimed in claim 31,
wherein said measuring assembly includes a stop block
movable between a first position in which said stop
5 block engages said window covering and a second
position in which said stop block is remote from said
window covering.

33. An apparatus as claimed in claim 30,
wherein said pocket of said cutting blade faces said
10 end of said window covering to be cut and said stop
block.

34. An apparatus as claimed in claim 1,
wherein said apparatus includes a measuring assembly
adjacent said cutting blade for measuring said
15 specified length of said window covering.

35. An apparatus as claimed in claim 34,
wherein said measuring assembly includes a stop block
movable between a first position in which said stop
block engages said window covering and a second
20 position in which said stop block is remote from said
window covering.

36. An apparatus as claimed in claim 34,
wherein said measuring assembly includes an instrument
for measuring said window covering.

37. An apparatus as claimed in claim 36,
25 wherein said instrument includes a ruler.

ABSTRACT OF THE DISCLOSURE

An apparatus for cutting window coverings having head rails and bottom rails to specified lengths includes a base having a top surface and a frame overlying the top surface. The frame is mounted to the base and the frame and the top surface of the base define a receiving area therebetween for receiving the window covering. The apparatus also includes a cutting assembly slidably mounted to the frame for sliding along a movement axis toward and away from the receiving area. The movement axis is diagonal to the top surface of the base. A cutting blade is connected to the cutting assembly and includes a cutting edge facing the receiving area. A driver, such as a rack and pinion gear assembly, is connected to the frame and is in engagement with the cutting assembly. Operation of the driver imparts sliding motion to the cutting assembly to move the cutting blade diagonally through the receiving area for cutting the window covering to the specified length.

DECLARATION OF UTILITY OR DESIGN PATENT APPLICATION

ATTORNEY'S DOCKET NO.: SPRINGS 3.0-024

As a below-named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name;

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

CUTTING APPARATUS FOR WINDOW COVERINGS AND METHODS THEREFOR the specification of which

☐ is attached hereto

☒ was filed on April 3, 1998 as United States Application Number or PCT International Application Number 09/054,845 and was amended on _____ (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment specifically referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in Title 37, Code of Federal Regulations, § 1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, § 119(a)-(d) of any foreign application(s) for patent or inventor's certificate or § 365(a) of any PCT international application which designated at least one country other than the United States of America, listed below and have also identified below any foreign application for patent or inventor's certificate, or any PCT international application having a filing date before that of the application on which priority is claimed:
